Reliability, IPC & NCAB
1. What is reliability?
2. What is IPC?
3. NCAB & IPC
4. IPC Class 3 – wants vs. needs
1. What is reliability?
Bad reliability can be caused when:

- Those within the supply chain have low knowledge / interest of the product
- Decision are made within manufacturing without being based upon fact
- There is bad process control – leads to very clear errors or “almost errors” (difficult to detect!)
- Specifications are unclear
- Focus on price instead of cost
RELIABILITY
An example of how bad reliability can cost

208 pieces of a 10 layer board
• Sourced: Directly within Europe
• Criteria: Shortest lead time
• Price: Unknown.

Result = Suspected black pad

COST OF THE CLAIM
€300,000
RELIABILITY

Good reliability more likely to be achieved when:

• There is good process control within the process.
• Those involved in the supply chain know the product demands and the necessary conditions for manufacture.
• There is a correct and clear specification.
• The producer is transparent about the level of delivery, design factors and construction process.
RELIABILITY

Good reliability is secured by

• Selecting a ‘serious’ and well-known producer.
• Making decisions based upon fact.
• Specifications relate to the demand of the end product – know what does and does not affect the functionality of the product.
• Refer to a well-known and updated standard, whilst ensuring it is understood and followed.
• Learning and understanding the demands.
2. What is IPC?
IPC

The organization

• Founded in 1957, IPC is basically a non commercial, member-driven, standard organization.

• Originally the meaning of IPC was “the Institute of Printed Circuits” but IPC is now referenced by “Association Connecting Electronic Industries” and covers most fields in electronics.

• It is an organization with thousands of members.
Why standards?
When ordering an apple, you expect an apple and not a banana!

For whom?
For everyone who wishes to receive what is expected (no surprises!) they should know what is defined as expected.

Example:
We all have probably bought something, which not lived up to our expectations!

The consequences can be extremely costly as well as ‘painful’!
Conformance to requirements

"Every product has a requirement, a specification, a description of what is expected. When this is met, it has achieved quality. Assuming that the requirement actually describes what the customer really expects or needs."

*defined by P. Crosby*
• Help to secure that we / the customer gets what is expected through defining exactly what is acceptable – there of minimizing risks.

• Make the conversation between customer & suppliers through a common understanding.

• Are capable of securing different quality or reliability levels.

• Enables a correct and compatible cost level.

It goes for everything – from the size of a breakfast egg to the strength of a wing on an aircraft!
3. IPC & NCAB
IPC & NCAB

Why IPC?

NCAB has chosen IPC as the base standards for PCB’s since 2004. As mentioned earlier, IPC is a “living” organization and is updating and releasing new standards on a frequent basis. This is even more important now, with the fast development of the electronics industry.
IPC & NCAB

IPC Standards are specified into three classes:

Class 1: General Electronic Products
• Consumer products, some computer and computer peripherals
• Cosmetic imperfection are not important
• Major requirement is function of the completed printed board.
IPC & NCAB

IPC Standards are specified into three classes:

Class 2: Dedicated Service Electronic Products

- Communication equipment, sophisticated business machines, and instruments
- High performance and extended life is required, and for which uninterrupted services is desired, but is not critical.
- Certain cosmetic imperfections are allowed.
IPC Standards are specified into three classes:

**Class 3: High Reliability Electronic Products**
- Continue performance is critical
- Life support
- Equipment downtime cannot be tolerated
- Often used for: Medical, military, aerospace, automotive
Do you need to specify a higher classification of IPC with advanced constructions or designs (i.e. class 3)?

No, IPC:s different classes have nothing to do with how advanced the boards are, but rather with the reliability demands that are placed upon the end product.

A higher IPC classification does not necessary relate to advanced boards or designs, but it should always relate to, or be considered for boards or designs, that have advanced purposes!
Consider the two PCB’s below

2 Layer PCB

Standard FR4 material (IPC 4101/ 21)

Tin lead finish.

Purpose: Control board for coolant system in Nuclear power station

8 Layer HDI Flex rigid PCB

High performance FR4 (IPC 4101/126)

ENIG finish with hard gold ‘hot pluggable contacts.

Purpose: Camcoder.
The standards and demands can be divided into three parts:

1. Design and Capability driven
2. Process-control driven
3. Verification driven
Design and capacity driven

- Annular rings
- Conductor imperfections
Annular rings Measurement of External Annular Ring
Conductor imperfections

Acceptable – Class 3

- Holes are not centered in the lands, but the annular ring measures 0.050 mm [0.0020 in] or more.
- The minimum external annular ring may have 20% reduction of the minimum annular ring at the measurement area due to defects such as pits, dents, nicks, pinholes, or splay.
Process-control driven

- Drilling and plating quality
- Surface finish thicknesses
IPC & NCAB / PROCESS-CONTROL DRIVEN

Surface finish thickness

Acceptable - Class 3
• Wicking does not exceed 80 μm [3,150 μin].

Acceptable - Class 2
• Wicking does not exceed 100 μm [3,937 μin].

Acceptable - Class 1
• Wicking does not exceed 125 μm [4,921 μin].

**Note 1.** Index Value is associated to the A.O.L. value. If a particular product is determined to be “critical” by the user and a smaller index value is required, the user shall designate the requirement in the procurement document and should state the “critical” requirement on the master drawing. **Denotes inspect entire lot.**

Acceptance Testing & Frequency

Note 1. Number in parentheses is the AQL level.

Note 2. Measurement location must be 30% larger than collimated source.

Note 3. All via structures shall be represented in the thermally stressed evaluations. Unique construction (e.g., blind, buried, unfilled through-hole, filled through-hole, etc.) and plating steps define a via structure.

Note 4. For Class 2 product, the degree of breakout may be assessed by methods other than horizontal microsection.

Note 5. The A and B or 2 A/B test coupons shall be taken from opposite corners of the manufacturing panel and in opposing axes (one in the “x” axis and the other in the “y” axis).

Note 6. For Type 1 and Type 2 printed boards, visual or AOI inspection may be used in lieu of electrical testing.

Note 7. PTH solderability testing not required for Type 2 double-sided printed boards without PTHs.

Note 8. Microsectioning for PTH evaluation not required for Type 2 double-sided printed boards without PTHs.
Structural Integrity Verification (Microsection)

Figure 3-14  Microsection Rotations for Breakout Detection

Figure 3-15  Comparison of Microsection Rotations

Copyright by IPC
Pictures by permission of IPC
An example:
When a production volume of 91-150 production panels of a 4 layer board, the checking of internal annular rings for class 3 demands 250 micro-Sectioning.

Note
This is verification on a product level – not to be mixed up with process control.
Does this approach / need make sense?

Yes, but only for extreme purposes or applications.
Verification vs. Process control

It is very important to understand the difference between verification on a product level and process control.

Process control is performed to secure the quality on different processes – such as plating parameters for example.

The verification on a product level is performed to verify that the process controls have worked well – more frequently with more demanding end-use conditions.

Good reliability is secured by having a good balance between verification on a product level and verification of the process. It cannot be achieved by sorting or screening on a product level.
4. IPC Class 3
– wants vs. needs
We can consider some base elements of the standards and adopt an AABUS approach.

AABUS – As Agree Between User and Supplier

This is the NCAB solution to balance the wants vs. needs question.
NCAB offers three different levels of IPC Class 3 boards

NCAB Level 1

- **Full** verification according to IPC-6012 table 4-2, 4-3
- Meeting end customer demands
- Limited supply chain options
- Extremely high cost
- Recommended for product with extreme demands (nuclear, deep sea, avionics applications)
NCAB offers three different levels of IPC Class 3 boards

NCAB Level 2
Production and verification according to IPC A 600, IPC 6012, micro-sectioning according to table 4-2 and 4-3 AQL 4.0. Except for less than 26 m-panels, two micro-sections per production batch applies.

• Meeting the majority of main end customers demands (also high reliability)
• Fairly cost effective
• Dual sourcing possible / less limitations on supply chain
• Recommended for product with very high demands (medicine, industrial)
NCAB Level 3
Production and verification according to IPC A 600, IPC 6012, two micro-sections/production batch.
• Meeting a specific end customers demands
• Cost effective
• Multi sourcing possible
• Recommended for most products (industrial, automotive)

Approved only for IPC Class 1 & 2

| Jove                |         |         |         | Not approved for IPC Class 3 |
Conclusions
Conclusions

• Good / qualitative sourcing is essential.
• Make sure all involved within the supply chain (internal and external) clearly knows and understands the demands.
• Be prepared to pay correct price – lowest price does NOT equal lowest total cost!
• Ensure that you are using a specification that is understandable and correct.
• Refer to well-known standards where applicable
• Choose a realistic process of verification on a product level based on the demands on the end product.

Do not over specify. This is as important as not under specifying.
